ADF&G TECHNICAL DATA REPORTS

This series of reports is designed to facilitate prompt reporting of data from studies conducted by the Alaska Department of Fish and Game, especially studies which may be of direct and immediate interest to scientists of other agencies.

The primary purpose of these reports is presentation of data. Description of programs and data collection methods is included only to the extent required for interpretation of the data. Analysis is generally limited to that necessary for clarification of data collection methods and interpretation of the basic data. No attempt is made in these reports to present analysis of the data relative to its ultimate or intended use.

Data presented in these reports is intended to be final, however, some revisions may occasionally be necessary. Minor revision will be made via errata sheets. Major revisions will be made in the form of revised reports.

SOUTHEASTERN ALASKA 1980 BROOD YEAR PINK (*ONCORHYNCHUS GORBUSCHA*)
AND CHUM SALMON (*O. KETA*) ESCAPEMENT SURVEYS
AND PRE-EMERGENT FRY PROGRAM

ABSTRACT

Pink salmon spawning escapements in Southeastern Alaska were highly variable in 1980 from district to district. Generally the southern Southeastern escapements were good in Districts 101, 102, and 103 and very poor in Districts 105, 106, and 107. The northern districts were good with the exception of District 114. Pre-emergent fry indices in 1981 were generally fair with above average fry indices in most districts.

INTRODUCTION

This report catalogs the Southeastern Alaska pink (*Oncorhynchus gorbuscha*) and chum salmon (*O. keta*) spawning escapements from the 1980 fishing season and the resulting pre-emergent fry indices for the spring of 1981. The escapement information is presented first, followed by the pre-emergent fry indices.

Escapements to major pink and chum salmon streams in Southeastern Alaska have been monitored annually by the Division of Commercial Fisheries of the Alaska Department of Fish and Game since just after statehood in 1959. Prior to 1959 the majority of escapement assessment was done by the U.S. Bureau of Commercial Fisheries (now National Marine Fisheries Service) which was then responsible for the management of the fisheries.

Pre-emergent studies have been conducted since 1965, now encompassing 95 streams sampled annually throughout Southeastern. When the program was first established only 35 streams were sampled in mostly their downstream (intertidal) areas. During the late 1960's a number of additional streams were added to the pre-emergent list, and in 1972 the upstream sampling effort was increased.

Information for previous years' data is available from the area biologists and from the Regional Office in Juneau. Computer listings are available for escapements from 1960-1980, and pre-emergent listings for 1965-1981.

METHODS

The Southeastern region is divided into 15 fisheries districts (Figure 1). For management purposes the districts are divided into five separate management areas (Haines, Juneau, Sitka, Petersburg, and Ketchikan) with each area being responsible for the fisheries in its districts and subdistricts.

Escapements

With over 2,500 anadromous streams in Southeastern Alaska the primary escapement survey method is by small plane, though a substantial number of surveys are conducted on foot. The Division of Commercial Fisheries currently operates one weir in northern Southeastern at Kadashan Creek in Tenakee Inlet and cooperates with the Fisheries Rehabilitation, Enhancement, and Development Division (FREDD) in the operation of one weir in southern Southeastern at Disappearance Creek in Cholmondeley Sound. Three other weirs are in operation: Klawock Creek, operated by FREDD; Little Port Walter, operated by the National Marine Fisheries Service (NMFS) in cooperation with FREDD; and Auke Creek weirs operated jointly by NMFS and FREDD. Surveys are summarized by subdistrict and district for final reporting.

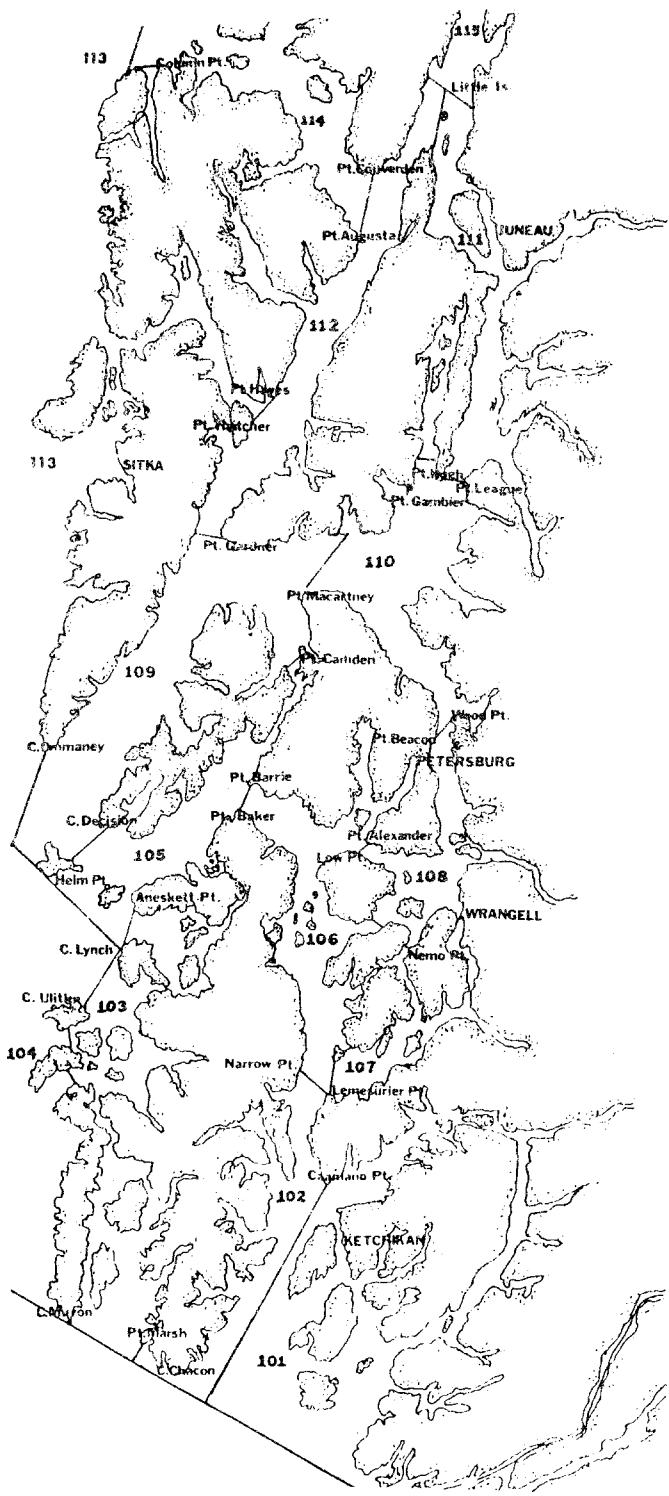

Figure 1. Southeastern Alaska regulatory districts.

Aerial estimates of salmon abundance are made for bays, stream mouths, and in the streams. Estimates for the streams include counts of both live and dead salmon by species. Aerial estimates are used primarily for in-season management of the purse seine fisheries. Foot surveys of salmon streams record estimates of live and dead salmon, by species, for both intertidal and upstream areas.

District escapement indices are calculated for pink salmon using the peak estimate for each stream. Of the four main management areas, Sitka, Petersburg, and Ketchikan use the following method for district escapement calculation.

- 1) Streams are categorized into "large" or "small" on the basis of their peak escapement estimates (large, over 10,000; small, less than 10,000), and the total escapement is calculated for each category.
- 2) The number of streams in each category is determined and the total of the two is subtracted from the total number of streams in the area. The result is the number of unsurveyed streams.
- 3) The average escapement to the small streams is then multiplied by the number of unsurveyed streams to give an estimate of escapement to all streams not surveyed.
- 4) The estimate of escapement to unsurveyed streams (#3 above) is added to the large and small stream escapement totals to give the final total escapement for the area.

The Juneau area (the fourth main management area) traditionally applies an estimate of 200 pink salmon to the unsurveyed streams and adds the same to the total of the peak estimates in the surveyed streams. The only other management area, Haines, does not calculate an escapement index for pink or chum salmon because all the major producing systems are surveyed.

District escapements for summer chum salmon are calculated by using the peak estimates from index streams. No expansion is made for unsurveyed systems because we have no way to estimate escapements into unsurveyed systems like we do for pink salmon. Since there are so few fall chum systems no escapement index is calculated.

Pre-emergent Fry Studies

In March, selected study areas in 95 streams are hydraulically sampled to estimate overwinter survival of pink and chum salmon fry as a basis for deriving a forecast of the resultant return run size. Over 5,000 samples of 0.2 square meters each are collected. Each sample is randomly located within an established study area. Study area size and the number of samples within each area varies according to the configuration of the individual stream channel, but most areas are sampled 35 to 40 times.

The forecast program utilizes portable hydraulic equipment to sample the fry abundance each year. The pump (Homelite XLS 1-1/2-4) draws water from the stream and forces it through a hose - probe assembly containing a venturi. The rate of flow is approximately 4,300 gph. The probe operator directs the air-water mix into the gravel inside a sampling net representing 0.2 square meters of spawning habitat. Salmon eggs, fry, and other light particles are lifted to the surface by the air bubbles and are swept by the current into the cod end of the net which is then emptied into a washpan for sorting and counting.

Within any study area riffle, between 5 and 45 samples are taken diagonally across the full width of the stream. The samples are subject to the guidelines displayed in Table 1.

Sampling is conducted in late February - early April after most of the freshwater mortality has occurred and just prior to the outmigration of most of the fry.

All data are keypunched and summarized by computer after sampling is completed.

The method for calculating district fry indices for northern and southern Southeastern varies. The southern area fry indices are simply the quotient of the total number of live fry and eggs divided by the area sampled in square meters. In the northern areas the district indices are first weighted by the relative strength of the escapement to the study streams within each brood year (Seibel 1972). The result is again weighted by the total estimated spawning area in each district. The separate methods are used because of the nature of the correlation between the resultant fry index and subsequent return.

RETURN

Pink Salmon Escapements

The 1980 pink salmon escapement to Southeastern Alaska streams was the second largest since 1960 but the distribution of the escapements was somewhat skewed. In southern Southeastern the total escapement of 6,570 thousand was 570 thousand over the escapement goal, the first time the goal has been exceeded since it was established in the early 1970's. Districts 101, 102, and 103 (Ketchikan management area) exceeded their cumulative escapement goal by over 34%, while streams in Districts 105, 106, and 107 (Petersburg management area) averaged 64% below the established escapement goal level. The escapements in Districts 101, 102, and 103 were considered excellent (Table 2) and represented a significant increase over the previous 20 years. Stream escapements in Districts 1021, 102, and 103 were well distributed and generally strong (Appendix Table 1).

In northern Southeastern pink salmon escapements were the lowest since 1976 with all districts falling well below escapement goal levels (Table 3). Escapements to District 114 streams represented only 15.8% of the desired

1980	428	396	208	517	495	79	2,123

escapement goal for the district; the other five districts achieved somewhat better escapements, averaging 47% of the established escapement goal.

Chum Salmon Escapements

The total 1980 Southeastern summer chum salmon escapement of 238.4 thousand was better than the parent year escapement (153.0 thousand), but below escapements achieved in the 1960's and early 1970's. The commercial harvest was well above any since 1974 with a total harvest of over 2.4 million; 1.6 million in the southern districts and 0.8 in northern Southeastern.

In southern Southeastern the chum salmon escapement of 75.1 thousand (Table 4) was just above the recent 20-year average of 71.5 thousand. The majority of the recorded summer chum salmon to the southern districts occurred in District 101 area streams which, in 1980, had a total of 52.2 thousand. The index stream in District 102 (Harris River) had no adult chum return in 1980 (Appendix Table 2). District 103 streams had a total of 1.6 thousand, down considerably from the parent year escapement of 19.0 thousand.

The district escapements in northern Southeastern were, without exception, above parent year escapement levels with a total of 132.3 thousand (Table 5), up from the parent year escapement of 75.9 thousand. The districts showing the most dramatic improvement were District 110, which increased from 1.6 thousand to 12.8 thousand, and District 114, which increased from 11.8 thousand to 31.6 thousand.

Fall chum salmon escapements were generally poor in 1980. Some of the systems like Disappearance Creek realized fair escapements but all systems could have accommodated much larger escapements.

Pre-emergent Fry Indices

The pre-emergent fry results for pink salmon were generally favorable but the chum salmon fry indices were very poor overall.

Pink Salmon Pre-emergent Fry Index:

The 1981 pink salmon fry index in both northern and southern Southeastern exceeded those experienced in the past 2 years (Tables 6 and 7). The index in the northern end was the fourth largest since the program was initiated. In the southern districts the fry index was not as high as might be expected from the record level escapements the previous fall.

In northern Southeastern, all districts except 109 and 114 had above average fry indices. The District 109 index of 335.8 fry per square meter was by far the highest observed since 1966 when the program was first initiated. The District 111 index of 104.0 fry per square meter was the second largest observed in the 16-year study period. Individual streams were highly variable (Appendix Table 3) but the overall average in the northern area was very encouraging.

In southern Southeastern, only District 106 had an exceptionally high fry index. The high overall index in District 106 can be attributed to two streams, Eagle Creek and 108 Creek in Whale Pass (Appendix Table 3). The other districts in the south end were generally disappointing particularly considering the parent year escapements.

Chum Salmon Pre-emergent Fry Index:

The chum salmon pre-emergent fry index in 1981 was below the recent 15-year average in northern and southern Southeastern. Overall, however, the 1981 district indices were generally above the 1980 indices (Tables 8 and 9).

In the northern districts, the two districts with relatively good indices were Districts 109 and 114. The District 109 index was the second largest since 1965 and the 1981 index in District 114 has only been exceeded twice in the same period.

With the exception of District 5 the southern districts chum salmon fry indices were very poor by comparison with earlier years. The low indices are not inconsistent with the trend in chum salmon escapements in southern Southeastern.

Table 8. Northern Southeastern chum salmon fry index by district and year.

Year	District 109	District 110	District 111	District 112	District 113	District 114	Total
